Esterel Compilation

## The 5-Minute Review Session

- 1. How does the constructive Boolean logic (intuitionistic logic) differ from classical Boolean logic?
- 2. What is the relationship between 1. logical correctness, 2. acyclicity, 3. constructiveness, 4. delay insensitivity?
- 3. In hw synthesis, which Esterel statements introduce registers?
- 4. In the context of Esterel, what is *reincarnation*? What is *schizophrenia*?
- 5. How is schizophrenia dealt with in classical programming languages? Which problems does schizophrenia cause in hw synthesis?

## The 5-Minute Review Session

- 1. In the context of Esterel, what is reincarnation?
- 2. What is *schizophrenia*?
- 3. What is a simple solution to the schizophrenia/reincarnation problem?
- 4. What is the approach by Tardieu and de Simone?
- 5. How do these approaches compare?

#### Esterel Compilation

Automata-Based Compilation Netlist-Based Compilation Control-Flow Graph-Based Compilation Experimental Comparison

# **Compiling Esterel**

- Semantics of the language are formally defined and deterministic
- Compiler must ensure that generated executable behaves correctly w.r.t. the semantics
- Challenging for Esterel

The following material is adapted with kind permission from Stephen Edwards (http://www1.cs.columbia.edu/~sedwards/)

## **Compilation Challenges**

#### Concurrency

- Interaction between exceptions and concurrency
- Preemption
- Resumption (pause, await, etc.)
- Checking causality
- Reincarnation (schizophrenia)
  - Loop restriction generally prevents any statement from executing more than once in a cycle
  - Complex interaction between concurrency, traps, and loops can make certain statements execute more than once

#### Automata-based Compilation

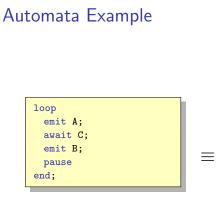

- Given Esterel program P and an input event I, the SOS inference rules introduced earlier produce an output event O and a program derivative P'
  - From P' and subsequent input event I', can produce another program derivative P'' and further output event O'
  - Can view this as sequence of state transitions—from state P to state P' to state P'' etc.
- Inference rules guarantee that set of states is finite (Finite State Machine, FSM)
- First compiler simulated an Esterel program in every possible state and generated code for each one

#### Automata-Based Compilation

Note: Strictly speaking, the state of an Esterel program—i.e., what must be remembered from one tick to the next—includes the following:

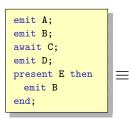

- 1. The set of program counter values where the program has paused between cycles
- 2. Presence status of signals accessed via pre operator
- 3. Values of valued signals
- 4. Values of variables
- 5. Any state kept in the host language

Only the program counters are reflected in states of FSM

<pre>void tick() {</pre>
<pre>static int state = 0;</pre>
sigtype $A = B = 0;$
<pre>switch (state) {</pre>
case 0:
A = 1;
<pre>state = 1;</pre>
break;
case 1:
if (C) {
B = 1;
<pre>state = 0;</pre>
}
break;
}
}

### Automata Example

<pre>switch (state) {</pre>
case 0:
A = 1;
B = 1;
<pre>state = 1;</pre>
break;
case 1:
if (C) {
D = 1;
if (E) B = 1;
state = 2;
}
break;
case 2:
}

#### First State

 A, B, emitted, go to second state

#### Second state

- if C is present, emit D, check E & emit B & go on
- otherwise, stay in second state

#### Third state

Terminated

#### Assessment of Automata Compilation

- ③ Very fast code
- Internal signaling can be compiled away
- © Can generate a lot of code because
  - Concurrency can cause exponential state growth
  - *n*-state machine interacting with another *n*-state machine can produce n<sup>2</sup> states
- Language provides input constraints for reducing state count
  - "these inputs are mutually exclusive" relation A # B # C
  - "if this input arrives, this one does, too" relation D => E

## Automata Compilation

- Not practical for large programs
- Theoretically interesting, but doesn't work for most programs longer than 1000 lines
- All other techniques produce—in general—slower code

## Netlist-Based Compilation

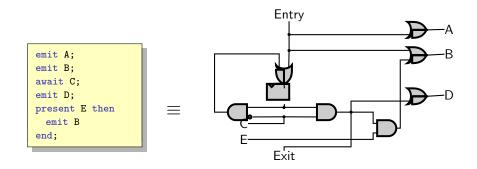

#### Second key insight:

 Esterel programs can be translated into Boolean logic circuits Netlist-based compiler:

Translate each statement into a small number of logic gates

- A straightforward, mechanical process
- Follows circuit semantics defined earlier
- Generate code that simulates the netlist

### Netlist Example

## Assessment of Netlist Compilation

#### Scales very well

- Netlist generation roughly linear in program size
- Generated code roughly linear in program size
- © Good framework for analyzing causality
  - Semantics of netlists straightforward
  - Constructive reasoning equivalent to three-valued simulation
- Serribly inefficient code
  - Lots of time wasted computing ultimately irrelevant results
  - Can be hundreds of time slower than automata
  - Little use of conditionals

# Netlist Compilation

- Currently the only solution for large programs that appear to have causality problems
- Scalability attractive for industrial users

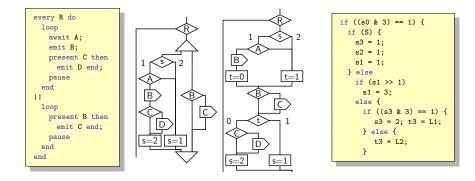

#### Control-Flow Graph-Based

#### Third key insight:

Esterel looks like a imperative language, so treat it as such

- Esterel has a fairly natural translation into a concurrent control-flow graph
- Trick is simulating the concurrency
- Concurrent instructions in most Esterel programs can be scheduled statically
- Use this schedule to build code with explicit context switches in it

## The CFG Approach

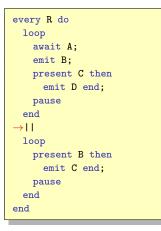

## Step 1: Build Concurrent CFG

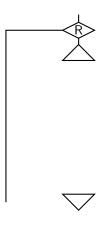

→every R do	
loop	
await A;	
emit B;	
present C then	
emit D end;	
pause	
end	
11	
loop	
present B then	
emit C end;	
pause	
end	
$\rightarrow$ end	

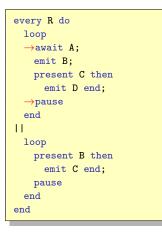

## Add Threads

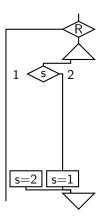

#### Split at Pauses

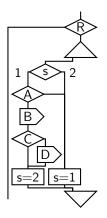

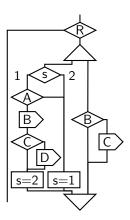

#### Add Code Between Pauses

```
every R do
→loop
\rightarrow await A;
\rightarrow emit B;
\rightarrow present C then
\rightarrow emit D end;
\rightarrow pause
\rightarrowend
11
  loop
  present B then
     emit C end;
   pause
  end
end
```

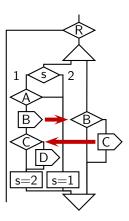

## **Build Right Thread**

```
every R do
 loop
    await A;
  emit B;
   present C then
    emit D end;
   pause
 end
11
→loop
\rightarrow present B then
   emit C end;
\rightarrow
→ pause
\rightarrowend
end
```

#### Step 2: Schedule

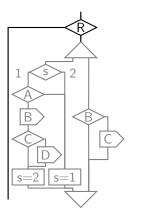

```
every R do
 loop
   await A;
   emit B;
   present C then
    emit D end;
   pause
 end
11
 loop
  present B then
    emit C end;
   pause
 end
end
```

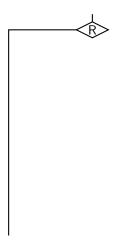

# Step 3: Sequentialize

- Hardest part: Removing concurrency
- Simulate the Concurrent CFG
- Main Loop:
  - For each node in scheduled order,
  - Insert context switch if from different thread
  - Copy node & connect predecessors

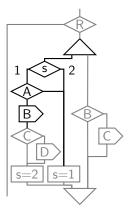

## Run First Node

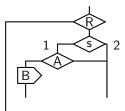

Esterel Compilation

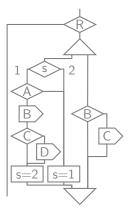

## Run First Part of Left Thread

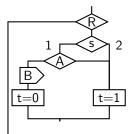

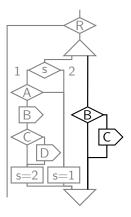

## Context switch: Save State

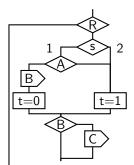

# Run Right Thread

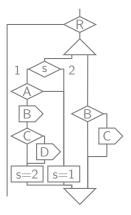

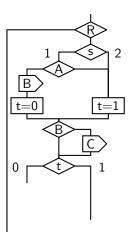

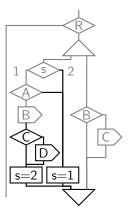

**Esterel Compilation** 

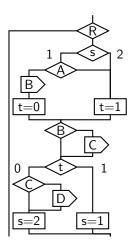

## Context Switch: Restore State

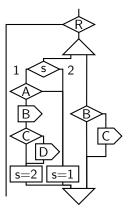

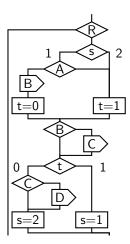

# Resume Left Thread

# Step 3: Finished

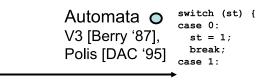

#### Assessment of Control-flow Approach

- Scales as well as the netlist compiler, but produces much faster code, almost as fast as automata
- © Not an easy framework for checking causality
- Static scheduling requirement more restrictive than netlist compiler
  - This compiler rejects some programs that others accept
- Extension: Pre-process constructive Esterel programs with cycles into equivalent non-cyclic programs [Lukoschus/von Hanxleden 2007]
  - Extends applicability of compilation approaches such as the CFG-based approach

## **Existing Esterel Compilers**

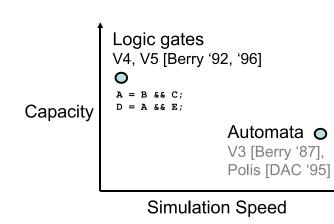

#### Simulation Speed

Edwards 2001

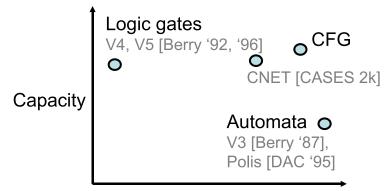

### **Existing Esterel Compilers**

## **Existing Esterel Compilers**

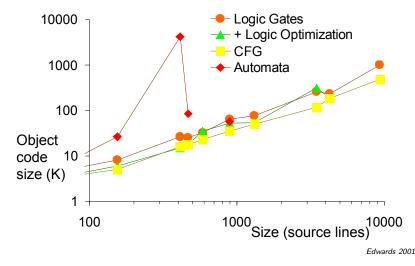

# Simulation Speed

Edwards 2001

#### Speed of Generated Code

#### Size of Generated Code

### Summary

Esterel compilation techniques:

- Automata
  - Fast code
  - Doesn't scale
- Netlists
  - Scales well
  - Slow code
  - Good for causality
- Control-flow
  - Scales well
  - Fast code
  - Bad at causality
