The 5-Minute Review Session

- 1. How does the constructive Boolean logic (intuitionistic logic) differ from classical Boolean logic?
- 2. What is the relationship between 1. logical correctness, 2. acyclicity, 3. constructiveness, 4. delay insensitivity?
- 3. In hw synthesis, which Esterel statements introduce registers?
- 4. In the context of Esterel, what is *reincarnation*? What is *schizophrenia*?
- 5. How is schizophrenia dealt with in classical programming languages? Which problems does schizophrenia cause in hw synthesis?

Overview

Esterel Compilation

Automata-Based Compilation Netlist-Based Compilation Control-Flow Graph-Based Compilation Experimental Comparison

CAU

Automata-Based Compilation Netlist-Based Compilation Control-Flow Graph-Based Compilation Experimental Comparison

Compiling Esterel

- Semantics of the language are formally defined and deterministic
- Compiler must ensure that generated executable behaves correctly w.r.t. the semantics
- Challenging for Esterel

The following material is adapted with kind permission from Stephen Edwards

(http://www1.cs.columbia.edu/~sedwards/)

Automata-Based Compilation Netlist-Based Compilation Control-Flow Graph-Based Compilation Experimental Comparison

Automata-based Compilation

- Given Esterel program P and an input event I, the SOS inference rules introduced earlier produce an output event O and a program derivative P'
 - From P' and subsequent input event I', can produce another program derivative P'' and further output event O'
 - Can view this as sequence of state transitions—from state P to state P' to state P'' etc.
- Inference rules guarantee that set of states is finite (Finite State Machine, FSM)
- First compiler simulated an Esterel program in every possible state and generated code for each one

Compilation Challenges

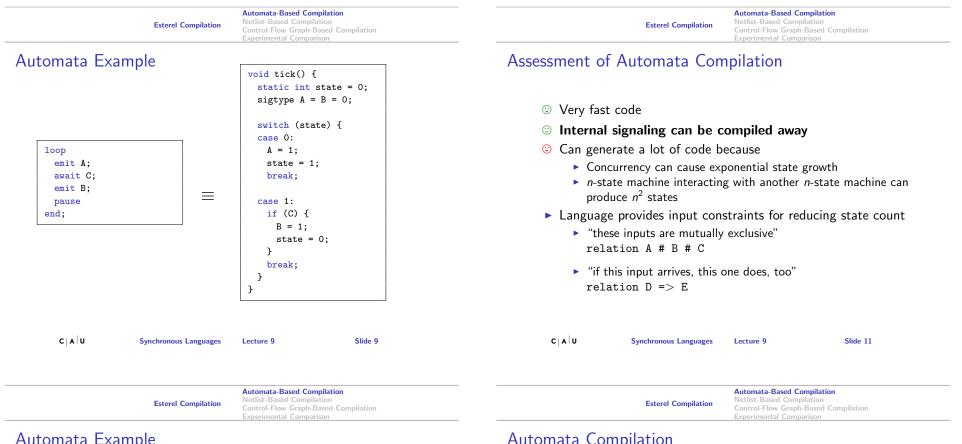

- Concurrency
- Interaction between exceptions and concurrency
- Preemption
- Resumption (pause, await, etc.)
- Checking causality
- Reincarnation (schizophrenia)
 - Loop restriction generally prevents any statement from executing more than once in a cycle
 - Complex interaction between concurrency, traps, and loops can make certain statements execute more than once

Automata-Based Compilation

Note: Strictly speaking, the state of an Esterel program—i.e., what must be remembered from one tick to the next—includes the following:

- 1. The set of program counter values where the program has paused between cycles
- 2. Presence status of signals accessed via pre operator
- 3. Values of valued signals
- 4. Values of variables
- 5. Any state kept in the host language

Only the program counters are reflected in states of FSM

Automata Example	<pre>switch (state) { case 0: A = 1; B = 1; state = 1; break; case 1: if (C) { D = 1; if (E) B = 1; state = 2; } break; case 2: }</pre>	 First State A, B, emitted, go to second state Second state if C is present, emit D, check E & emit B & go on otherwise, stay in second state Third state Terminated
------------------	---	---

Automata Compilation

- Not practical for large programs
- Theoretically interesting, but doesn't work for most programs longer than 1000 lines
- ► All other techniques produce—in general—slower code

Automata-Based Compilation

Netlist-Based Compilation

Netlist-Based Compilation

Automata-Based Compilation Netlist-Based Compilation Control-Flow Graph-Based Compilation Experimental Comparison

Assessment of Netlist Compilation

Second key insight:

Esterel programs can be translated into Boolean logic circuits

Netlist-based compiler:

- Translate each statement into a small number of logic gates
 - ► A straightforward, mechanical process

Esterel Compilation

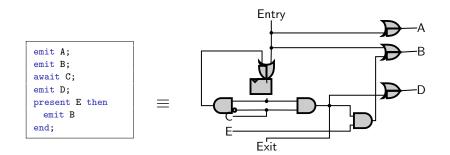

- Follows circuit semantics defined earlier
- Generate code that simulates the netlist

$\hfill \odot$ Scales very well

- Netlist generation roughly linear in program size
- Generated code roughly linear in program size
- © Good framework for analyzing causality
 - Semantics of netlists straightforward
 - Constructive reasoning equivalent to three-valued simulation
- © Terribly inefficient code
 - Lots of time wasted computing ultimately irrelevant results
 - Can be hundreds of time slower than automata
 - Little use of conditionals

Netlist Example

Netlist Compilation

- Currently the only solution for large programs that appear to have causality problems
- Scalability attractive for industrial users

Esterel looks like a imperative language, so treat it as such

• Esterel has a fairly natural translation into a concurrent

• Concurrent instructions in most Esterel programs can be

• Use this schedule to build code with explicit context switches

Control-Flow Graph-Based Compilation

Automata-Based Compilation

Netlist-Based Compilation

Control-Flow Graph-Based

► Third key insight:

control-flow graph

scheduled statically

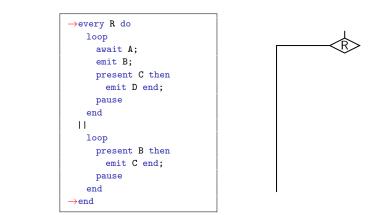

Trick is simulating the concurrency

Automata-Based Compilation Netlist-Based Compilation **Control-Flow Graph-Based Compilation**

Step 3: Sequentialize

Automata-Based Compilation Netlist-Based Compilation Control-Flow Graph-Based Compilation Experimental Comparison

Run First Part of Left Thread

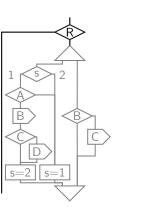

- ► Hardest part: Removing concurrency
- Simulate the Concurrent CFG
- Main Loop:
 - For each node in scheduled order,
 - ► Insert context switch if from different thread
 - Copy node & connect predecessors

Assessment of Control-flow Approach

CAU

Capacity

Existing Esterel Compilers

- Scales as well as the netlist compiler, but produces much faster code, almost as fast as automata
- © Not an easy framework for checking causality

Synchronous Languages

Esterel Compilation

Esterel Compilation

- © Static scheduling requirement more restrictive than netlist compiler
 - This compiler rejects some programs that others accept
- Extension: Pre-process constructive Esterel programs with cycles into equivalent non-cyclic programs [Lukoschus/von Hanxleden 2007]
 - Extends applicability of compilation approaches such as the CFG-based approach

Speed of Generated Code

Summary

Esterel compilation techniques:

Esterel Compilation

- Automata
 - Fast code
 - Doesn't scale
- Netlists
 - Scales well
 - Slow code
 - Good for causality
- Control-flow
 - Scales well
 - Fast code
 - Bad at causality
