Synchronous Languages

Lecture 10

Slide 1

SyncCharts (Safe State Machines)
From Esterel to SyncCharts

#### The 5-Minute Review Session

- 1. Why does constructiveness analysis matter in circuit design?
- 2. How do cyclic and acyclic circuits differ?
- 3. How do we analyze constructiveness of a cyclic circuit?
- 4. How do we extend Boolean functions to three-valued logic?
- 5. Are TVFs monotonic? What does that mean?

#### The 5-Minute Review Session

- 1. In constructiveness analysis, how can we minimize the number of gate evaluations?
- 2. How do the computational complexities of *Malik* vs. *Shiple* compare?
- 3. How do we extend the constructiveness analysis to circuits with *latches*?
- 4. What is the computational problem class of the constructiveness analysis problem?
- 5. What are Core SCCharts?

A Tour of SyncCharts

# Harel-Statecharts vs. SyncCharts—Similarities

SyncCharts are made up of elements common to most Statecharts dialects:

- States
- ► Initial/terminal states
- ► Transitions
- Signals/Events
- Hierarchy
- Modularity
- Parallelism

# Harel-Statecharts vs. SyncCharts—Differences

SyncCharts differ from other implementations of Statecharts:

- Synchronous framework
- Determinism
- ► Compilation into backend language Esterel
- ▶ No interpretation for simulations
- No hidden behaviour
- Multiple events
- Negation of events
- ► No inter-level transitions

## Simple Sequential Automaton

#### SyncChart:

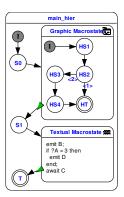

# main I /A S1 /B S2

## Elements:

- States:
  - Regular state (circle)
  - ► Terminal state (doubled circle)
  - ► Hierarchic state (box with rounded edges)
- ► Transitions:
  - Arrows with labels
- Connectors:
  - ► Colored circles with single letters

C | A | U Synchronous Languages Lecture 10 Slide 6 C | A | U Synchronous Languages Lecture 10 Slide 8

#### Hierarchic States

SyncCharts know four types of states:

- 1. Simple States: Carry just a label.
- 2. Graphic Macrostates: Encapsulates a hierarchy of other states, including further graphic states.
- 3. Textual Macrostates: Contain statements of the Esterel language. They are executed on entry of the state.
- 4. Run Modules: Include other modules.

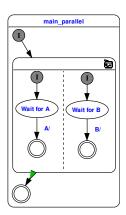

Transitions are **not** allowed to cross the boundaries of graphic macrostates. This is in contrast to other modelling tools.

C | A | U Synchronous Languages Lecture 10 Slide 9

SyncCharts (Safe State Machines)
From Esterel to SyncCharts

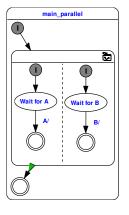

Comparison with Harel's Statecharts
Simple Automata, Hierarchy, Concurrency/Parallelism

#### Parallel States

- Dashed lines (horizontal or vertical) separate parallel executed states inside a graphic macrostate.
- ► Each segment may be segmented into further parallel segments, but iterative segmentation does not introduce additional hierarchy. All parallel segments in a graphic macrostate are at the same level.

#### Parallel States

- ► A transition outside the graphic macrostate with normal termination is activated, when all parallel segments have reached their terminal state.
- ▶ If just one segment does not have one or if it is not reached, then the normal termination transition will never be activated.

C | A | U Synchronous Languages Lecture 10 Slide 11

From Esterel to SyncCharts

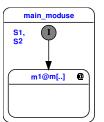

Comparison with Harel's Statecharts Simple Automata, Hierarchy, Concurrency/Parallelism A Tour of SyncCharts

### Modules

A module like this with an interface:

input I; output 0;

... can be used as a Run Module with these signal bindings:

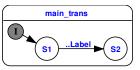

signal S1 / I; signal S2 / O

## Syntax of Transition Labels

Informal syntax of a transition label between states S1 and S2, all elements are optional:

# factor trigger {condition} / effect

#### Basic activation and action:

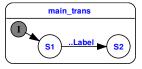

- ▶ trigger is an expression of signal presence like "A or B"
- ► Enclosed in braces is the condition. It is a data expression over signal values or variables like "?A=42"
- ▶ Behind a single "/" follows the *effect*' as a list of emitted signals if the transition is executed. Multiple signal names are separated with ",".

C | A | U Synchronous Languages Lecture 10 Slide 13

SyncCharts (Safe State Machines)
From Esterel to SyncCharts

Comparison with Harel's Statecharts Simple Automata, Hierarchy, Concurrency/Parallelism A Tour of SyncCharts

## Syntax of Transition Labels

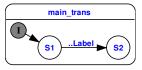

Informal syntax of a transition label between states S1 and S2, all elements are optional:

# factor trigger {condition} / effect

#### Extensions:

- "#" is the flag for an immediate transition
- "factor" is the (natural) number of ticks a transition must be active before it is executed. These active ticks does not need to be consecutive, but S1 must be active all the time.

# Transition Labels: Examples

The following label examples belong to the transition originating at S1 and leading to S2:

► A/B

After entering S1 the signal A is tested from the next tick on. If A is present, then B is emitted in the same tick and state S2 is entered.

- ► /B
  After enabling S1, B is emitted in the next tick and S2 is entered.
- ➤ 3 A/ The transition is executed, if S1 is active consecutively and signal A is present for 3 times.

C | A | U Synchronous Languages Lecture 10 Slide 15

SyncCharts (Safe State Machines)
From Esterel to SyncCharts

Comparison with Harel's Statecharts Simple Automata, Hierarchy, Concurrency/Parallelism A Tour of SyncCharts

Slide 16

## Transition Labels: Examples

► #A/

If S1 is entered, signal A is tested from the same tick on. If A is present in the tick S1 is entered then state S2 is entered in the same tick.

► {?A=42}/

The transition is executed, if the (valued) signal A carries the value 42. A does not need to be present for this test.

► A {?A=42}/

This test succeeds if A is present and carries the value 42.

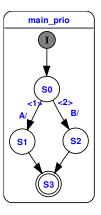

- ▶ A and (B or C)/ Logical combination of signal presence.
- ► {?A=10 and (?B<3 or ?C=1)}/
  Logical combination of value tests.
- ► /A(2), B(4) Emission of multiple valued signals.

Simple Automata, Hierarchy, Concurrency/Parallelism
A Tour of SyncCharts

#### Transition Priorities

- ▶ When more than one transition departs a state, an automatic (but editable) priority ordering is established.
- ► The transition labels are evaluated according to their priority.
- The first label that succeeds activates its transition.
- Low numbers mean high priority.

A Tour of SyncCharts

Transition Types

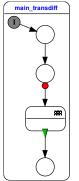

SyncCharts feature four different types of transitions: They are differentiated by a symbol at the arrow root:

- Initial connector: Initial arc
   Initial arcs connect the initial connectors of the chart with the other states.
- 2. No symbol: Weak abort
  When the trigger/condition of the transition
  is enabled, then the actions of the originating
  state in the current tick are executed for a
  last time, then the transition action, and the
  entry action of the new state.
  In other words:

The old state can "express it's last will".

## Transition Types

- Red bullet: Strong abort
   The action for the current tick of the old state is not executed. Only the transition action and the entry action of the new state is executed.
- 4. Green triangle: Normal termination
  This transition can be used to exit macro states. It is activated when the macro state terminates.

All these transition types must not be confused with "immediate" or "delayed" evaluation of the transition label (label prefix "#").

CAU

Synchronous Languages

Lecture 10

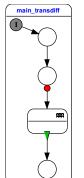

Slide 19

SyncCharts (Safe State Machines)
From Esterel to SyncCharts

Comparison with Harel's Statecharts Simple Automata, Hierarchy, Concurrency/Parallelism A Tour of SyncCharts

## Transition Types and Labels

Some transition types have restrictions on their labels:

- ► Initial arc: These are always "immediate," therefore the additional flag "#" is not needed.
- Weak abort: No restrictions.
- Strong abort: No restrictions.
- Normal termination:
   They support no triggers or conditions
   because they are activated by the termination of the originating state. The immediate flag is not used either.

C | A | U Synchronous Languages Lecture 10 Slide 18 C | A | U Synchronous Languages Lecture 10 Slide 20

## Transition Types and Priorities

The type of a transition interacts with it's priority:

► Strong abort: Highest priority

► Weak abort: Middle priority

► Normal termination: Lowest priority

# Local Signals and Variables

#### Local signals

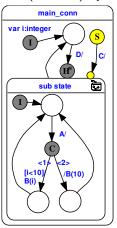

- Defined in the body of a graphical macrostate
- ► Shared between parallel threads

#### Local variables

Not shared

#### Connectors

This (artificial) SyncChart demonstrates all four connector states:

- Initial connector
  - Activated at activation of the macrostate
  - Only departing transitions permitted
  - ► All connected transitions are "immediate"

#### Conditional connector

- ► All departing transitions are "immediate"
- ► One departing "default" transition without condition must be present.

A Tour of SyncCharts

#### Connectors

This (artificial) SyncChart demonstrates all four connector states:

# Suspend connector

- ▶ The suspend state is always active.
- ► Only one departing transitions is permitted.
- ► The transition can only hold a trigger expression.
- ► The "immediate" flag can be enabled on demand.
- When the transition is activated, then the target state is (strongly) suspended.

Step 3: Optimizations

#### Connectors

This (artificial) SyncChart demonstrates all four connector states:

## History connector

- ► This connector is directly attached to macrostates
- ▶ Only incoming transitions can connect.
- ➤ The previous state of the macrostate is restored when it is entered through a history connector.

# Equivalence of SyncCharts and Esterel

- ► Esterel and SyncCharts look different
- ► However, underlying model of computation/semantics are equivalent
- ▶ Both are based on synchrony hypothesis
- ► Can translate one into the other

#### Overview

SyncCharts (Safe State Machines)

SyncCharts (Safe State Machines)
From Esterel to SyncCharts

Step 1: Transform Esterel to SyncChart Step 2: Reduce to Fully Graphical SyncChart

Step 3: Optimizations

## Step 3: Optimizations

#### Motivation

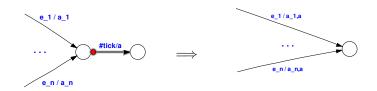

- ► Automatic synthesis produces "verbose" modules
- ► However, also human modelers (esp. novices) may produce sub-optimal models

#### Notes:

- ▶ It may be a matter of style/opinion what "optimal" means
- ► However, consistency in style is desirable in any case—and standardized optimization rules help to achieve this

#### Step 3: Optimizations

Removing Simple States

#### Precondition: State must be transient

C | A | U Synchronous Languages Lecture 10 Slide 39

SyncCharts (Safe State Machines)
From Esterel to SyncCharts

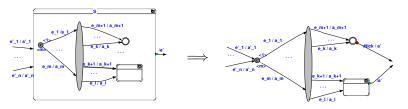

Step 1: Transform Esterel to SyncChart

Step 2: Reduce to Fully Graphical SyncChart

arts to Esterel Step 3: Optimizations

## Step 3: Optimizations

Flattening Hierarchy

#### Preconditions:

- ▶ no abort originates from S
- ▶ S has no local signals
- + further rules to remove conditionals, combine terminal states, remove normal terminations

C | A | U Synchronous Languages Lecture 10 Slide 38 C | A | U Synchronous Languages Lecture 10 Slide 40

Slide 41

SyncCharts (Safe State Machines) From Esterel to SyncCharts From SyncCharts to Esterel Examples Structural Translation Ordering States

# From SyncCharts to Esterel

Motivation

- ▶ Intermediate Step from SyncChart to C-Code (or VHDL, ...)
- ► This is what Esterel Studio does
- ► This translation is one possibility to define the semantics of SyncCharts.
- ► The following description of the translation is based on [André 1996] and the synthesis actually done by Esterel Studio (excluding the optimizations done by Esterel Studio)

#### Basic Idea

- Structural Induction on SyncChart
- ▶ Simple-States become await
- ▶ Macro-States become abort
- ► Parallel stays parallel
- Problem: How to order states?

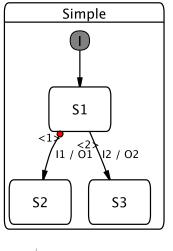

C | A | U Synchronous Languages Lecture 10 Slide 43

C | A | U Synchronous Languages Lecture 10 Slide 42

Examples Structural Translation Ordering States SyncCharts (Safe State Machines) From Esterel to SyncCharts From SyncCharts to Esterel

Examples
Structural Translation

# Not-so-simple Hierarchy

nothing; % state Parent trap sc\_end\_automaton1 in nothing; loop % state C1 await case (I) do nothing; % state C2 exit sc\_end\_automaton1 case (tick) do emit O end await end loop end trap ; nothing; halt

## Not-so-simple Cycle

CAU Synchronous Languages Lecture 10

Slide 49

SyncCharts (Safe State Machines) From SyncCharts to Esterel

Structural Translation

## Components

The translation is performed on a variant of the And-/Or-Tree

Reactive Cell

► State + Outgoing transitions

▶ State can contain macrostate

Region

► Multiple connected Reactive Cells

Macrostate ► Nonempty set of Regions

We have to introduce new signals and traps

- trap end\_automaton for normal termination
- ▶ signal goto\_s for each state s in a region

CAU Slide 48 CAU Slide 50 Synchronous Languages Lecture 10 Synchronous Languages Lecture 10

Structural Translation

#### Macrostate

```
[
run Region_1
||
...
||
run Region_n
]
```

C | A | U Synchronous Languages Lecture 10 Slide 51

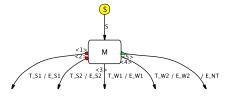

While this translation seems obvious, it is only possible due to strong restrictions on terminal states, e.g.,

- ► No outgoing transitions
- ▶ No *on inside* actions

SyncCharts (Safe State Machines) From Esterel to SyncCharts From SyncCharts to Esterel

Structural Translation
Ordering States

#### Reactive Cell

```
module Cell
output trans_1 ... trans_5
abort
 weak abort
   suspend
     run M;
     emit E_NT;
     emit trans_5;
   when S;
 case T_W1 do emit E_W1;
           emit trans_3;
 case T_W2 do emit E_W2;
           emit trans_4;
 end abort
case T_S1 do emit E_S1;
         emit trans_1;
case T_S2 do emit E_S2;
         emit trans_2;
end abort
```

C | A | U Synchronous Languages Lecture 10 Slide 52

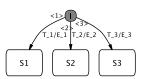

- S: suspend
- ► T\_S1/E\_S1 . . . : Triggers/effects of strong abortions
- ► T\_W1/E\_W1 . . . : Triggers/effects of weak abortions
- ► E\_NT: Effect of normal termination
- ▶ trans\_1 ...: helper signal to indicate which transition is taken

#### Notes:

- ▶ In this example, the effects are emissions of some signal; in general, the effects can be more complex
- ▶ For simple states, run M is nothing.
- ▶ If no normal termination exists, we have to add a halt after the run. Hence for simple states, which never have normal terminations, the abort is equivalent to an await.
- ► The module interface may in general contain more signals than the ones shown here.

Structural Translation

## Region Initialization

```
present

case T_1 then emit E_1;
emit goto_1;
case T_2 then emit E_2;
emit goto_2;
case T_3 then emit E_3;
emit goto_3;
end present
```

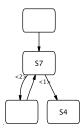

C | A | U Synchronous Languages Lecture 10 Slide 53

Note that the disjunction of the triggers must be a tautology—*i. e.*, it must be ensured that one of the transitions will always be triggered.

SyncCharts (Safe State Machines)
From Esterel to SyncCharts
From SyncCharts to Esterel

Structural Translation
Ordering States

#### Region Continuation

```
signal goto_S1, ..., goto_Sn in
trap end_automaton
 loop
   trap L in
     present goto_S7 then
       signal \alpha in
         emit \alpha;
         run Cell7[goto_S4/trans_1,...];
         exit end_automaton % for terminal states
         present \alpha else exit L end present
       end signal
     end present;
     halt
   end trap
  end loop
end trap
end signal
```

C | A | U Synchronous Languages Lecture 10 Slide 54

- ▶ The default behavior is, in each loop iteration, to enter a cell, based on the goto signals, to spend some time in that cell, and then to re-enter the loop via the exception L.
- However, we also want to handle transient states. The signal  $\alpha$  is used to prevent illegal instantanous re-entries of the loop. If  $\alpha$  is still present when it is tested, the corresponding cell has been entered and left again instantaneously, and we are not allowed to re-enter the loop; instead, we continue execution of the same iteration of the loop body.
- When a terminal state is reached, no further behavior is possible, thus the whole region can be stopped; this is done by throwing the exception end\_automaton
- ▶ When a cell is run, we bind the transition signals according to the context of the cell. In this example, the transition signal trans\_1 of cell S7 becomes goto\_S4 of region Region2.
- ▶ The halt in the loop statement serves to assure the compiler that the loop is not instantaneous.

Examples Structural Translation Ordering States

## How to order the states of a Region?

- ▶ A state can be entered and left in the same tick
- ▶ Thus several states can be active in the same tick
- ▶ All immediate reachable states have to be later in the loop
- ► Could forbid immediate transitions
- ▶ This would make modeling more difficult
- ► All transitions form a dependence graph
- ▶ Remove all delayed abortions from this graph
- ▶ Note: normal terminations might be immediate
- ► This graph has to be acyclic!

C | A | U Synchronous Languages Lecture 10 Slide 55

If the graph contains a cycle, we could consider further details, to decide whether the circle can really occur, *e. g.*, whether normal termination can take place in the first tick.

SyncCharts (Safe State Machines) From Esterel to SyncCharts From SyncCharts to Esterel

Structural Translation
Ordering States

## Summary

- ▶ SyncCharts can be translated to Esterel, and vice versa
- ► Translation of SyncCharts to Esterel:
  - Structural induction of And-/Or-Tree
  - Macrostates, regions and reactive cells are translated separately
  - ► Challenge: unstructured control flow
- ▶ Translation from Esterel to SyncCharts:
  - Structural induction on Esterel code

Synchronous Languages

From SyncCharts to Esterel

- ▶ Resulting SyncChart has to be optimized to become readable
- ► Challenge: traps
